Furia Ninja

Private game database

Milestone 1 delivery report: database structure, application foundation and first interface

The login screen. Every page of the application sits behind it.

Screenshots in this document were taken from the running application. Any name starting with [DEMO] is a placeholder test entry, not real game information.

1. Summary

Milestone 1 is finished. The application now has a working foundation: a database designed for the full scope of the game, a private login with separate permissions for approved users and the administrator, a Spanish interface, and a first version of the screens that Milestones 2 and 3 will fill in.

I did not enter any real game data. Ninjas, equipment, jewelry and gems will come from the reference channels in the next milestone. The only content in the screenshots is clearly marked [DEMO] test data that I used to check that the screens work.

There is no Discord bot, no Discord connection and no automatic import of any kind, as agreed.

What is in place

- A database with every area from the brief: ninjas, roles, abilities, talents, effects, conditions, statistics, equipment, equipment sets, jewelry, jewelry sets, gems and set bonuses.
- A private login. Anyone who is not logged in is sent to the login page. Regular users can only look. Only the administrator can reach the admin area.
- Spanish as the default language, with all interface text kept in one place so another language can be added later.
- A main layout with header, logo, navigation and user area. It works on desktop, tablet and phone.
- Reusable pieces for showing conditional effects (for example an effect that only works with a certain nature) and talents where the player can only pick one.

2. How the database is organised

The main idea is to avoid big blocks of loose text. Each thing in the game is its own record, and records point to each other. That keeps the data searchable later, and a change in one place shows up everywhere.

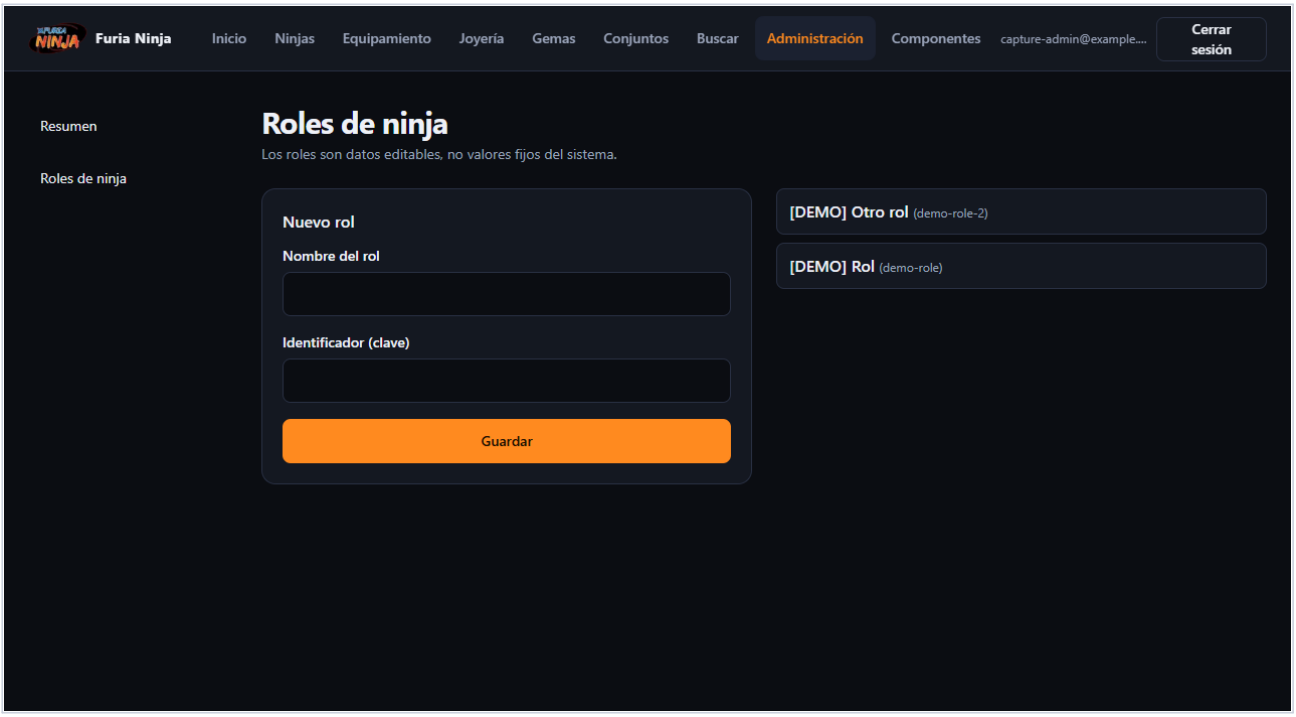

Area	What it holds
Ninjas and roles	Each ninja has a name, description, image and a role. Roles are normal records the administrator can add to, so Support, Assaulter and Vanguard are not hard coded and new roles can be created whenever the game needs them.
Abilities	Skills, passives, awakenings and attacks. The type is a record too, so new kinds can be added. A ninja can have any number of them.
Talents	Talents live in groups. A group says how many can be chosen. See section 4.
Statistics	HP, Attack, Speed, Final Damage and so on are records, not code. The administrator can add new ones later. Each statistic can be a percentage, a flat number or a multiplier.
Effects and conditions	One shared effect record is used by abilities, talents, equipment, set bonuses, jewelry and gems. Conditions attach to an effect, see section 4.
Equipment and sets	Pieces with a slot and a set. Each set bonus stores its own piece count, so 2, 4 and 6 are just data. A set could have a 3 piece bonus tomorrow without any change to the structure.
Jewelry and sets	Kept separate from equipment on purpose because the rules can differ. A jewelry bonus can ask for a number of pieces or for specific named items.
Gems	Gems with a type and their own effects.
Users	Accounts with a role, an active flag, and login sessions.

3. Login and permissions

The application is private. A visitor who is not logged in cannot open any page except the login screen.

There are two kinds of account. A regular approved user can log in, browse and view details, and nothing else. The administrator can do everything a user can, plus reach the admin area, where content will be created and edited in Milestone 3.

All of this is checked on the server every time. Hiding a button in the browser is never relied on. If a regular user types an admin address, they get a not found page, so the admin area does not even reveal that it exists. Passwords are stored as one way hashes, never as plain text, and no password or secret is written into the source code. The administrator email goes in a settings file and the password is supplied only when the account is created.

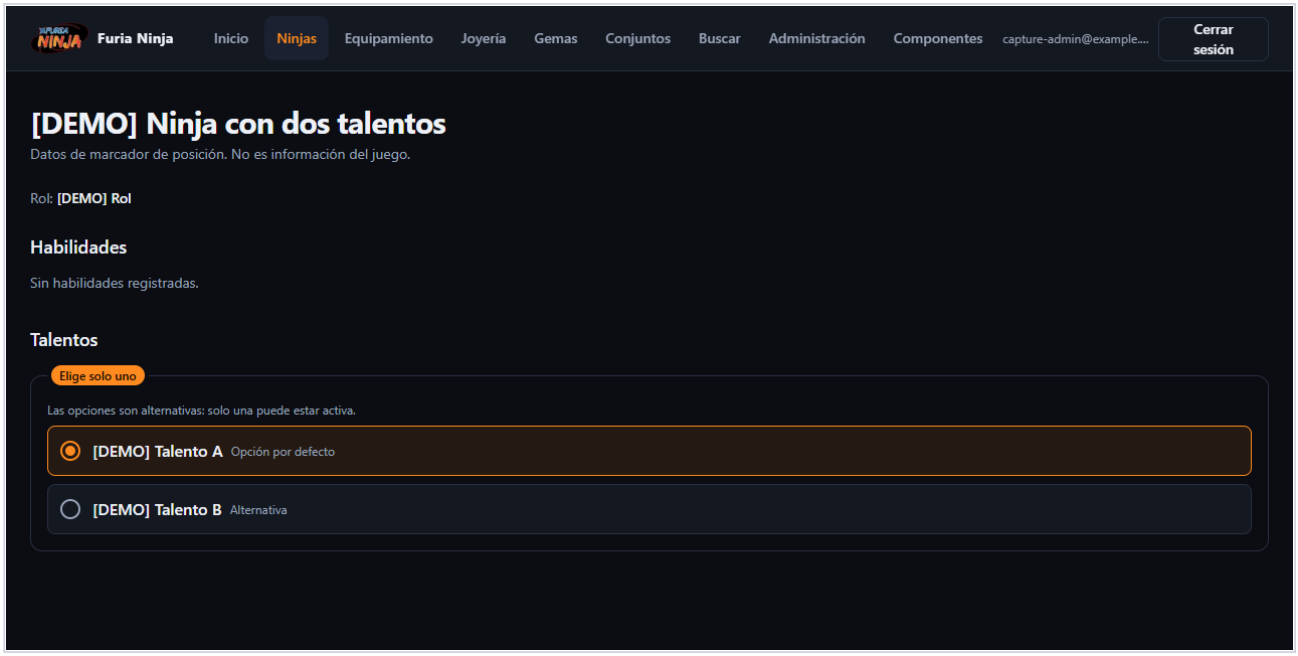

The admin area, with a small working example: creating a ninja role. It checks the permission on the server, validates the input and refuses duplicates. Milestone 3 will repeat this pattern for all content.

4. The two rules that matter most

Choose one talent

When a ninja has two talents and the player can only use one, they are stored as one group with two options and a rule that says only one can be active. They are not stored as two separate talents. The group can hold three or more options if a future ninja needs it. On screen the group is labelled "Elige solo uno" (choose only one), the options look like radio buttons, and the second option is marked as an alternative, so nobody reads them as both being active.

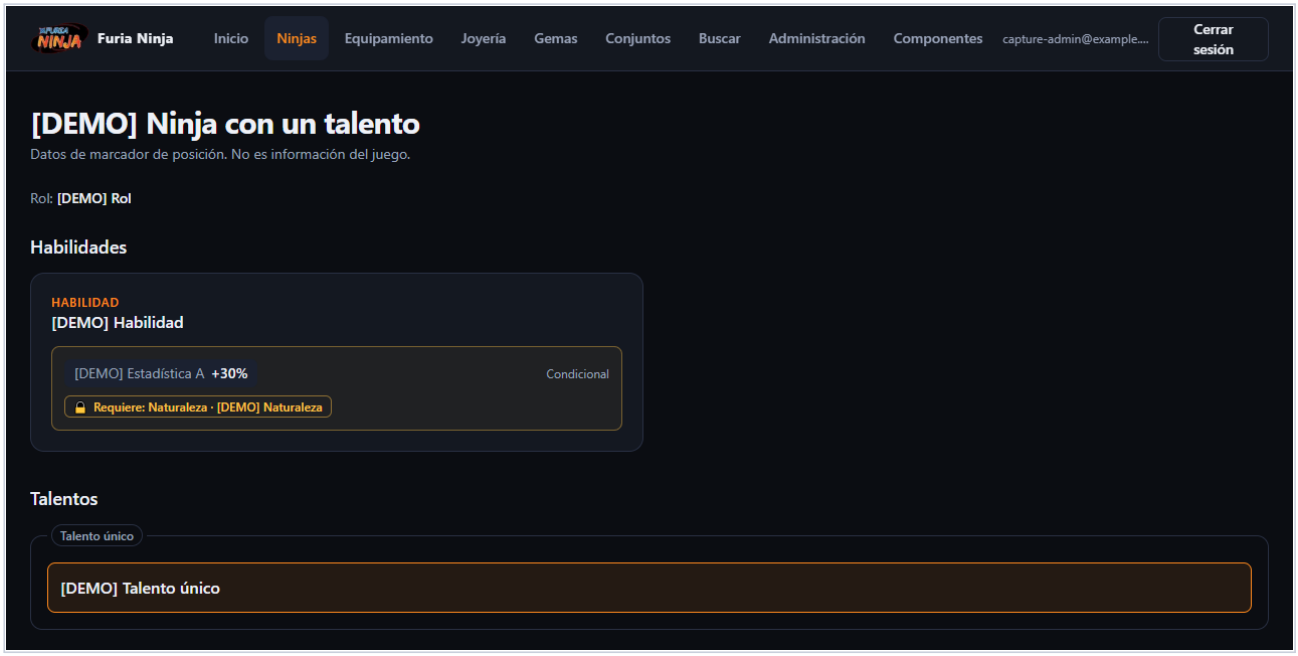

A ninja with two mutually exclusive talents. Test data.

Effects that only apply under a condition

Every effect can carry conditions. A condition has a kind (nature, role, target, trigger, status and so on), a value from a list the administrator manages (for example a specific nature), and whether it is required or excluded. Conditions can be grouped as alternatives, meaning "this nature or that nature". Chance and duration are stored on the effect itself. Nothing is built around one single nature rule, so new kinds of condition do not need a redesign.

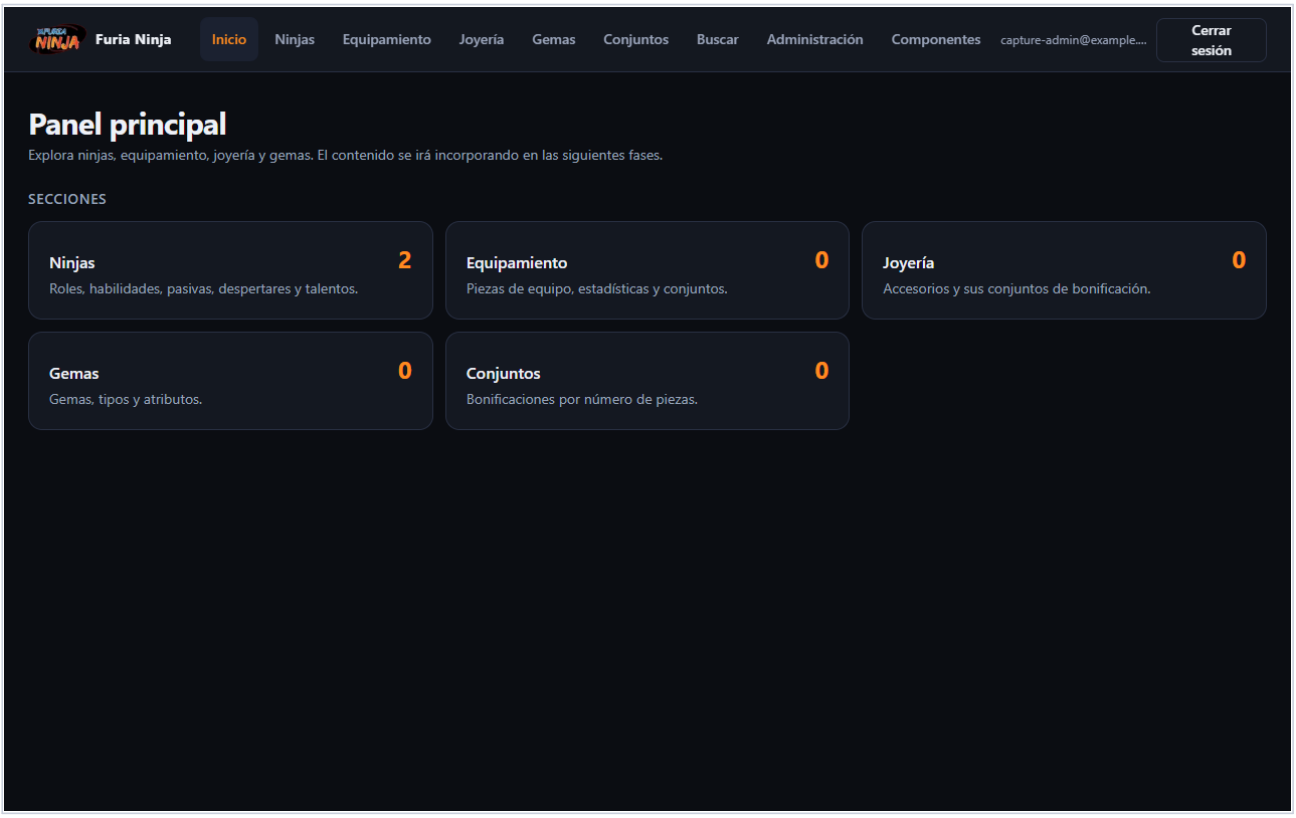

On screen, a conditional effect is never shown like a normal one. It gets a "Condicional" label, a lock icon and plain text such as "Requiere: Naturaleza". Unconditional effects say "Siempre activo". The meaning is in the words and the icon, not only in the color, so it stays clear on a phone and for people who do not see colors well.

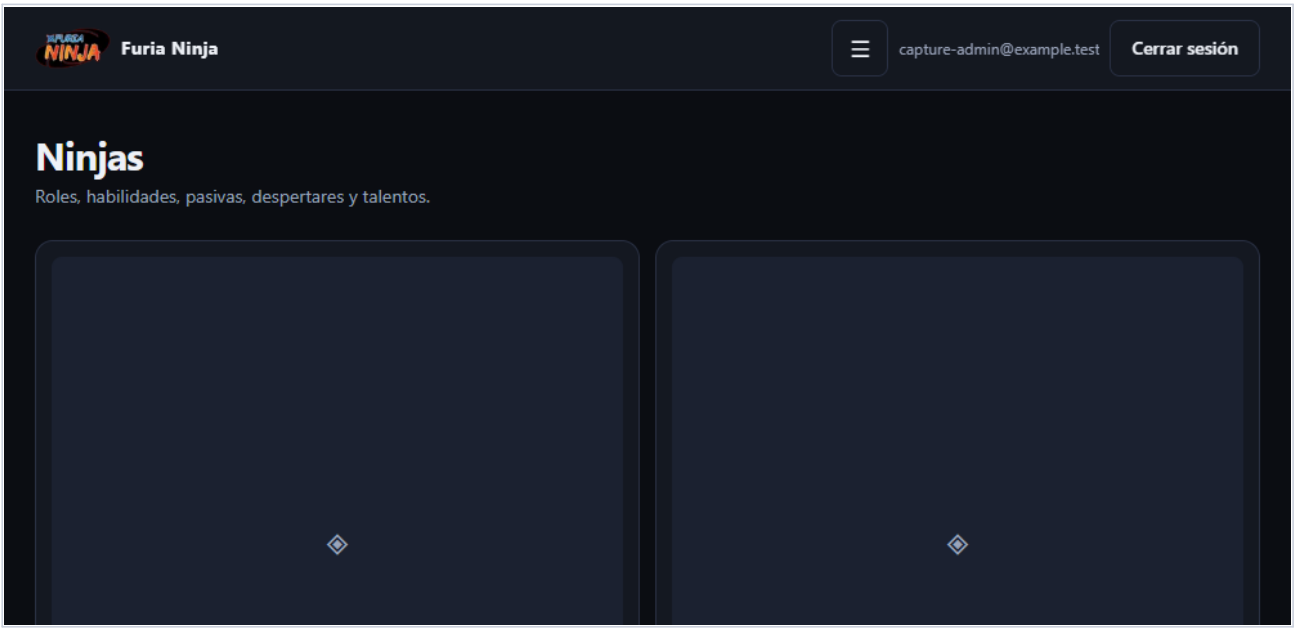

An ability whose +30% effect requires a nature. Test data.

5. The interface

The look is dark and clean, with the logo colors as the accent. The goal was a premium game database that is easy to scan and does not feel crowded.

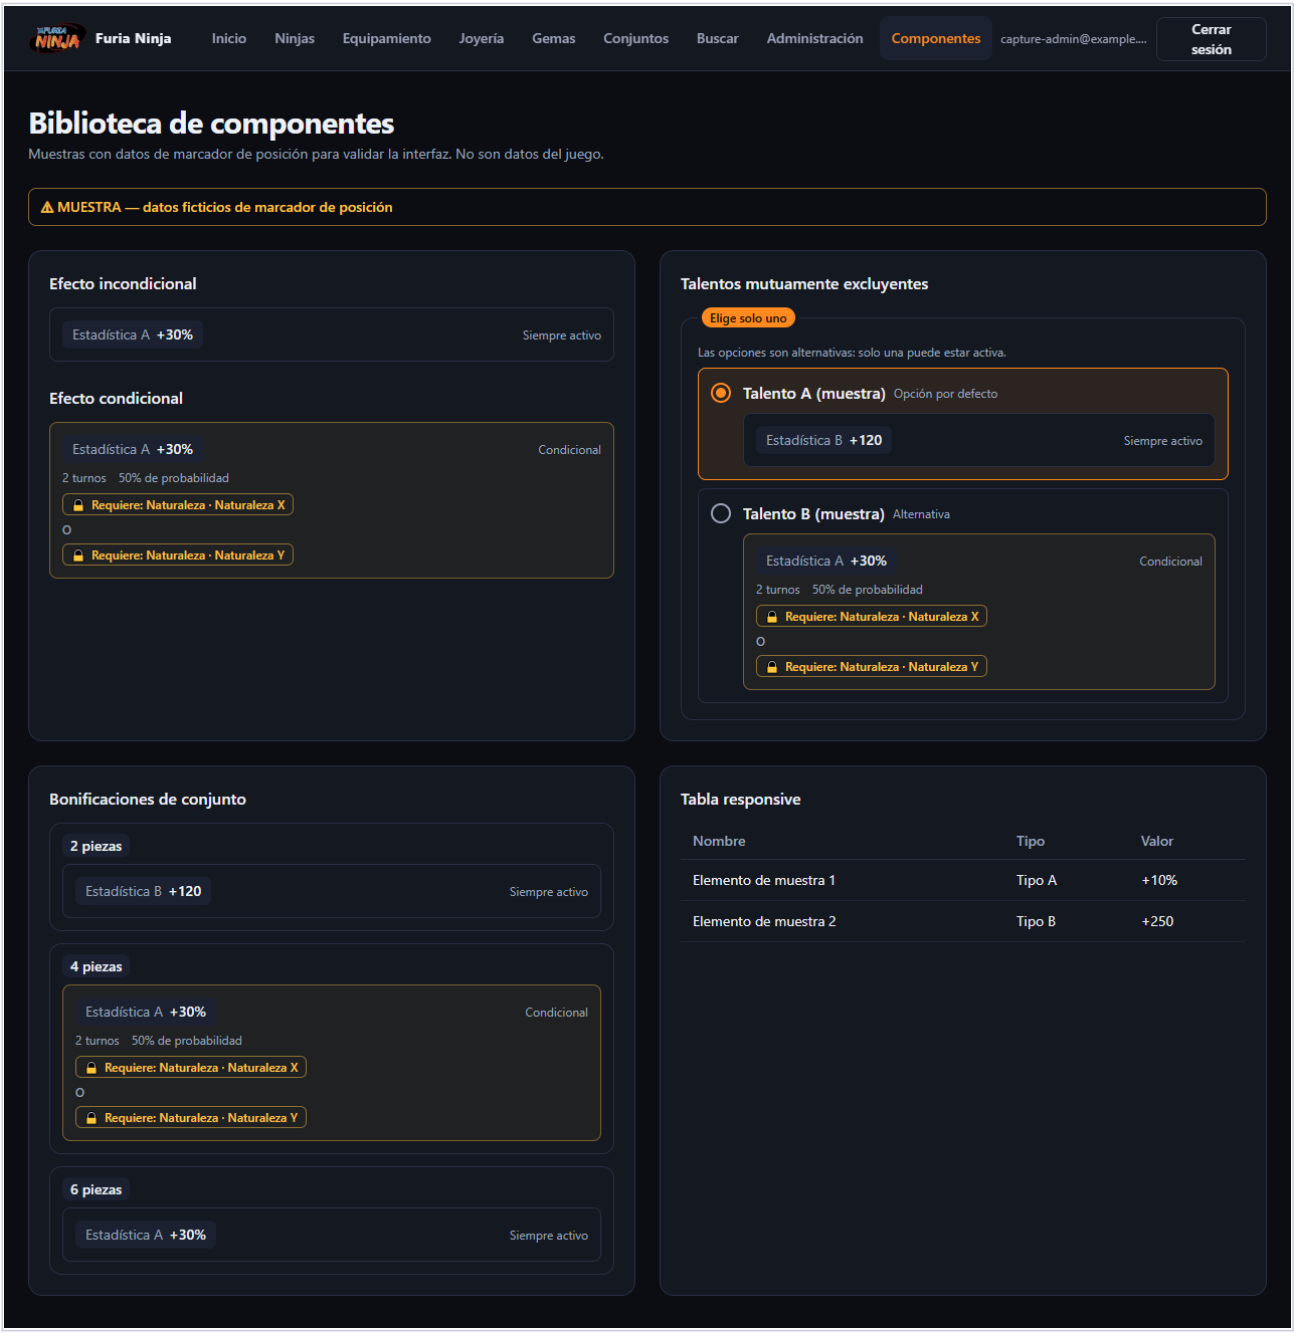

Home screen with the main sections and a count for each. The counts are real; they currently include test entries only.

The ninja list. With no content it shows a clear empty message instead of a blank page.

Component library

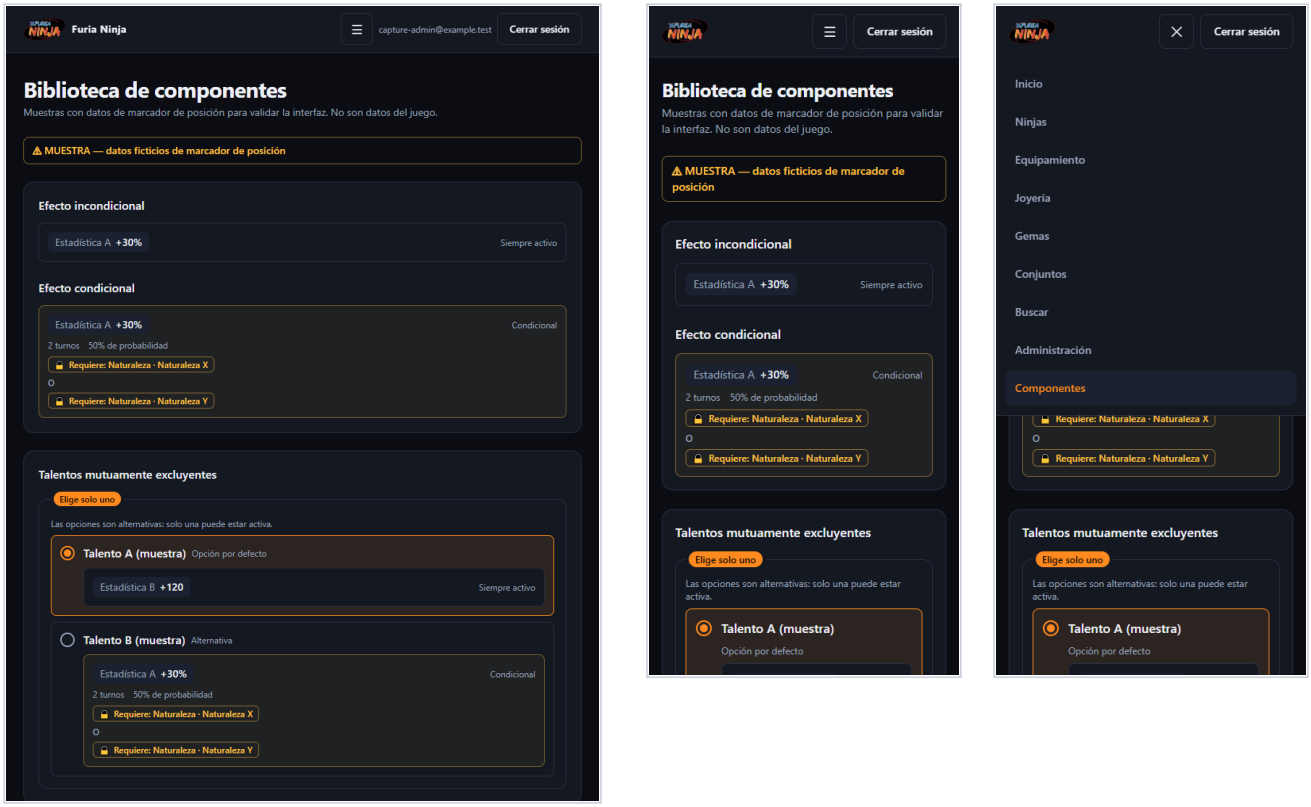

This page shows each reusable piece in one place: conditional and unconditional effects, mutually exclusive talents, set bonuses at 2, 4 and 6 pieces, and a table. It is labelled as sample data.

Component library with placeholder values.

6. Tablet and phone

The layout adapts to the screen. On a phone the navigation folds into a menu button and tables turn into stacked cards, so nothing needs sideways scrolling. I checked tablet and phone widths in a real browser and found no horizontal overflow on any page I tested.

Left to right: tablet width, phone width, phone with the menu open.

7. What I tested

Everything below was actually run, not assumed.

Check	Result
Automated tests	20 of 20 pass. They cover one talent, two exclusive talents, effects with and without a condition, a nature requirement, 2/4/6 piece equipment bonuses, a jewelry bonus with a different structure, and percentage and flat statistics.
Type checking	Clean, no errors.
Code style check	Clean, no warnings.
Production build	Succeeds.
Database setup	The migration creates the full structure from scratch without errors.
Login protection	Logged out visitors are redirected to login. A regular user gets a not found page on every admin address. A forged login cookie is rejected.
Real browser run	A wrong password shows a Spanish error. A correct login works. Creating a role works and a duplicate is refused. Logging out works.
Screen sizes	Desktop, tablet and phone checked, including the phone menu.

One bug turned up during testing and is fixed: after a wrong password the email field was being cleared. I also corrected a label that read "Elige entre 1 y 1" for a ninja with a single talent. It now says "Talento único".

8. Known limits

- There is no limit on login attempts yet. I recommend adding one before the site goes live.
- The talent selector is read only for now. The default option is shown as selected. Picking is for a later milestone.
- Opening a ninja page that does not exist shows the not found screen, but the browser still receives a normal status code. It does not change what the user sees.
- The database is a local file for development. A hosted database and a hosting provider are needed for production.

9. Next: Milestone 2

- Enter the real data for ninjas, equipment and jewelry by hand from the reference channels.
- Build the list and detail pages for equipment, jewelry, gems and sets.
- Add search and filters.
- Make the talent choice interactive.

To start, I need the content itself, as exported text or screenshots, plus the in game names for statistics, natures and roles. A few sample posts, for instance one ninja with two selectable talents and one equipment set, would let me check the structure against real content before the bulk entry begins. I do not need your Discord login, and I would rather not hold it.
